BD Series

1.5” – 4” (DN40-100) Back Pressure Regulators and Valves
FOR GAS, LIQUID AND MIXED PHASE SERVICE
Our performance.
Equilibar® back pressure regulators outperform the competition, particularly in applications with low flow rates, mixed phase fluids, corrosive media, or extreme temperatures.

Our people.
Every inquiry gets focused attention from our engineering team to determine the best possible product for your needs. Every back pressure regulator is hand assembled and tested to meet our stringent quality standards.

Our priorities.
Our goal is to exceed your expectations. In an industry where delivery times frequently exceed 6 weeks, we offer many of our standard products with delivery in about a week.

The Equilibar Difference

Traditional back pressure regulators set the upstream pressure with a spring. These designs utilize sliding seals and other moving parts that can introduce hysteresis and other undesired effects into a process. The Equilibar® back pressure regulator uses a thin, supple diaphragm as the only moving part. This allows frictionless operation without cracking pressure or hysteresis. The accuracy of the Equilibar® back pressure regulator is determined by the accuracy of the pilot setpoint.
How It Works

Simply load the Equilibar® back pressure regulator with a pilot pressure equal to your desired back pressure and the Equilibar does the rest. This pressure forces the flexible diaphragm down onto a plate of orifices. A rise in inlet pressure lifts the diaphragm up to allow excess pressure to be relieved through the outlet orifices. Similarly, a loss of pressure at the inlet causes the diaphragm to be pushed closer to the orifices, restricting flow and rebuilding pressure upstream.

Pilot operate your Equilibar® back pressure valve with an electronic pressure regulator for automated back pressure control. Or set the pilot pressure with a precision pressure reducing regulator for manual back pressure control.

**Performance Comparison**

**Traditional Spring-Type Regulators**

Pressure reducing regulators reduce a higher supply pressure at the inlet down to a regulated lower pressure at the outlet (downstream). Back pressure regulators work the opposite way. They regulate the inlet (upstream) pressure by opening up only as much as necessary to hold back the desired pressure at the inlet (upstream).

For most applications, the Equilibar BD meets performance expectations when controlled by a manual pressure reducing pilot regulator. However, for some automation applications, it is useful to have closed loop control using an external pressure transmitter. By using an electro-pneumatic regulator with external feedback, it is possible to automatically adjust the pilot setpoint based on the feedback from the pressure transducer.

The Equilibar BD Series valve provides numerous benefits over traditional control valves in these closed loop applications. Such benefits include extremely wide flow range, ultra fast reaction times, and ease of PID tuning.
Glove Box / Ventilation Control

The Equilibar BD Series regulator is a good choice for controlling gas pressures in glove boxes or other ventilation applications. The BD can be constructed with flexible diaphragm material for high sensitivity and accuracy at low pressures, even at relatively high flow rates.

Supply gas can be provided by a blower or other flow control means. Pilot setpoint pressure can be regulated by an electro-pneumatic regulator (shown) or manual spring regulator.

Fuel Cell Testing

The Equilibar® BD Series back pressure regulator is an excellent fit for fuel cell testing systems. An Equilibar BD is used to control the outlet pressure of the fuel cell while it is being performance tested.

Customers choose Equilibar valves because they accurately maintain pressure from really low flow rates up to very high flow rates; they work accurately at very low pressures where fuel cells operate; and they can easily handle wet, hot, corrosive exhaust gasses produced by the fuel cell.

Biogas System Pressure Control

Many wastewater treatment plants use anaerobic digestion to process their biological solid wastes, reducing landfill volumes and producing valuable biogas used to generate power. Controlling the biogas pressure that feeds a combustion engine is critical, especially because the flow rate coming out of the digester fluctuates.

Customers choose the Equilibar BD valve in this application because of its ability to maintain low pressure at high flows. The multiple orifice design also delivers fast response required for this process.
Manual Pilot Control Options

MANUAL CONTROL
Equilibar Precision Back Pressure Regulators get a pilot control signal using a fluid setpoint pressure (also called ‘reference’ or ‘pilot’ pressure) on the top port. This pilot fluid is typically compressed air or nitrogen.

Below are some popular pressure reducing regulators used to control the pilot signal for Equilibar back pressure regulators.

# Electronic Pilot Control

**PROCESS AUTOMATION**

Automating your process pressure is easily accomplished by using an electronic pressure regulator to provide the pilot setpoint pressure to the Equilibar dome-loaded back pressure regulator.

These devices are custom tuned on the bench to work perfectly with the Equilibar precision back pressure regulators or vacuum regulators.

Contact Equilibar or visit our website for assistance in choosing a pilot control system for your application.

---

1. All Equilibar units are tested to 150% of their rated pressure prior to shipment.
2. Designed according to ASME B31.3, which incorporates a 4X safety factor. Polymer models not recommended for compressible gas applications.
